**Definition 21.4:** A language $L$ is in **Polynomial Probabilistic Time (PP)** if there is a PTM $M$ such that:

- there is a polynomial function $f$ such that $M$ will always halt after $f(|w|)$ steps on all input words $w$,
- if $w \in L$, then $\Pr [M \text{ accepts } w] > \frac{1}{2}$,
- if $w \not\in L$, then $\Pr [M \text{ accepts } w] \leq \frac{1}{2}$.

**Definition 21.11:** A language $L$ is in **Bounded-Error Polynomial Probabilistic Time (BPP)** if there is a PTM $M$ such that:

- there is a polynomial function $f$ such that $M$ will always halt after $f(|w|)$ steps on all input words $w$,
- if $w \in L$, then $\Pr [M \text{ accepts } w] \geq \frac{2}{3}$,
- if $w \not\in L$, then $\Pr [M \text{ accepts } w] \leq \frac{1}{3}$.
**Algorithm:** For a polynomial \( p(x_1, \ldots, x_m) \)

- Randomly select a number \( k \in \{1, \ldots, 2^{2n}\} \)
- Randomly select \( a_1, \ldots, a_n \in \{1, \ldots, 3 \cdot 2^n\} \) (a total of \( O(n \cdot m) \) random bits)
- Evaluate the circuit modulo \( k \) to compute \( p(a_1, \ldots, a_m) \mod k \)
- Repeat this experiment for \( 4n \) times and accept if and only if the outcome is 0 in all cases

This leads to an error-probability of \( \leq \frac{1}{3} \) for polynomials that are non-zero, and an error probability of 0 for polynomials that are.
BPP and other classes
The neighbours of BPP

We have already observed that $P \subseteq BPP$.

Moreover, since $PP$ used less strict conditions on probabilities, we immediately get

$$BPP \subseteq PP \subseteq PSpace$$
The neighbours of BPP

We have already observed that $P \subseteq BPP$.

Moreover, since PP used less strict conditions on probabilities, we immediately get

$$BPP \subseteq PP \subseteq PSpace$$

Another interesting result is the following:

**Theorem 23.1 (Adleman’s\(^1\) Theorem):** $BPP \subseteq P/poly$

(remember that we also knew that $P \subseteq P/poly$ but not whether $NP \subseteq P/poly$)

\(^1\) Adleman is the A in RSA.
Theorem 23.1 (Adleman’s Theorem): \( \text{BPP} \subseteq \text{P}_{/\text{poly}} \)

**Proof:** By Theorem 21.12, any language in BPP is recognised by a PTM \( \mathcal{M} \) with error probability \( \leq \frac{1}{2^{n+1}} \). For an input of size \( n \), \( \mathcal{M} \) uses a polynomial number \( m \) of random bits \( r \in \{0, 1\}^m \) (verifier perspective on PTMs).
Proving Adleman’s Theorem

Theorem 23.1 (Adleman’s Theorem): $\text{BPP} \subseteq \text{P/poly}$

Proof: By Theorem 21.12, any language in BPP is recognised by a PTM $M$ with error probability $\leq \frac{1}{2^{n+1}}$. For an input of size $n$, $M$ uses a polynomial number $m$ of random bits $r \in \{0, 1\}^m$ (verifier perspective on PTMs).

- $r$ is bad for input $w \in \{0, 1\}^n$ if $M$ returns the wrong answer on $w$ for random bits $r$; otherwise $r$ is good for $w$.
Theorem 23.1 (Adleman’s Theorem): \( \text{BPP} \subseteq \text{P/poly} \)

Proof: By Theorem 21.12, any language in BPP is recognised by a PTM \( \mathcal{M} \) with error probability \( \leq \frac{1}{2^{n+1}} \). For an input of size \( n \), \( \mathcal{M} \) uses a polynomial number \( m \) of random bits \( r \in \{0, 1\}^m \) (verifier perspective on PTMs).

- \( r \) is bad for input \( w \in \{0, 1\}^n \) if \( \mathcal{M} \) returns the wrong answer on \( w \) for random bits \( r \); otherwise \( r \) is good for \( w \)

- Because of the error probability, there are \( \leq \frac{2^m}{2^{n+1}} \) bad strings for any \( w \)
**Theorem 23.1 (Adleman’s Theorem):** \( \text{BPP} \subseteq \text{P/poly} \)

**Proof:** By Theorem 21.12, any language in BPP is recognised by a PTM \( M \) with error probability \( \leq \frac{1}{2^{n+1}} \). For an input of size \( n \), \( M \) uses a polynomial number \( m \) of random bits \( r \in \{0, 1\}^m \) (verifier perspective on PTMs).

- \( r \) is **bad** for input \( w \in \{0, 1\}^n \) if \( M \) returns the wrong answer on \( w \) for random bits \( r \); otherwise \( r \) is **good** for \( w \)
- Because of the error probability, there are \( \leq \frac{2^m}{2^{n+1}} \) bad strings for any \( w \)
- In total, for all \( 2^n \) inputs, there are \( \leq 2^n \frac{2^m}{2^{n+1}} = \frac{2^m}{2} \) bad strings
Theorem 23.1 (Adleman’s Theorem): $\text{BPP} \subseteq \text{P/poly}$

Proof: By Theorem 21.12, any language in BPP is recognised by a PTM $\mathcal{M}$ with error probability $\leq \frac{1}{2^{n+1}}$. For an input of size $n$, $\mathcal{M}$ uses a polynomial number $m$ of random bits $r \in \{0, 1\}^m$ (verifier perspective on PTMs).

- $r$ is bad for input $w \in \{0, 1\}^n$ if $\mathcal{M}$ returns the wrong answer on $w$ for random bits $r$; otherwise $r$ is good for $w$.
- Because of the error probability, there are $\leq \frac{2^m}{2^{n+1}}$ bad strings for any $w$.
- In total, for all $2^n$ inputs, there are $\leq 2^n \frac{2^m}{2^{n+1}} = \frac{2^m}{2}$ bad strings.
- Therefore, there are strings $r$ that are good for all inputs.
**Theorem 23.1 (Adleman’s Theorem):** $\text{BPP} \subseteq \text{P/poly}$

**Proof:** By Theorem 21.12, any language in BPP is recognised by a PTM $\mathcal{M}$ with error probability $\leq \frac{1}{2^{n+1}}$. For an input of size $n$, $\mathcal{M}$ uses a polynomial number $m$ of random bits $r \in \{0, 1\}^m$ (verifier perspective on PTMs).

- $r$ is **bad** for input $w \in \{0, 1\}^n$ if $\mathcal{M}$ returns the wrong answer on $w$ for random bits $r$; otherwise $r$ is **good** for $w$.
- Because of the error probability, there are $\leq \frac{2^m}{2^{n+1}}$ bad strings for any $w$.
- In total, for all $2^n$ inputs, there are $\leq 2^n \frac{2^m}{2^{n+1}} = \frac{2^m}{2}$ bad strings.
- Therefore, there are strings $r$ that are good for all inputs.

Take one such universally good string $\hat{r}$; build a circuit for a deterministic verifier TM of inputs $w \# r$ as in Theorem 19.7; hardwire $\hat{r}$ as input for the certificate. □
BPP and the Polynomial Hierarchy

**Recall:** We have defined the polynomial hierarchy in two ways:

- Polytime ATMs with number of alternations bounded by a constant
- Oracle (N)TM that use oracles for lower levels of the hierarchy

For example, $\Sigma^P_2 = \text{NP}^{\text{NP}} = \text{NP}^{\text{coNP}}$, the languages recognised by polytime ATMs that begin their runs in an existential state and may alternate to a universal state later on.

One would not immediately expect that these classes are related to BPP.

---

Notes:
- Michael Sipser first showed that $\text{BPP} \subseteq \text{PH}$; Peter Gács then showed the theorem; Clemens Lautemann then gave the readable proof we will show – all in 1983.
- The result has been further strengthened since, suggesting that $\text{BPP}$ strictly smaller, but no relation to any other class we covered so far is known.

Markus Krötzsch, 16th Jan 2019 Complexity Theory
BPP and the Polynomial Hierarchy

**Recall:** We have defined the polynomial hierarchy in two ways:

- Polytime ATMs with number of alternations bounded by a constant
- Oracle (N)TMs that use oracles for lower levels of the hierarchy

For example, $\Sigma^P_2 = NP^{NP} = NP^{coNP}$, the languages recognised by polytime ATMs that begin their runs in an existential state and may alternate to a universal state later on.

One would not immediately expect that these classes are related to BPP, yet we have:

**Theorem 23.2 (Sipser-Gács-Lautemann Theorem):** $\text{BPP} \subseteq \Sigma^P_2 \cap \Pi^P_2$

**Notes:**

- Michael Sipser first showed that $\text{BPP} \subseteq \text{PH}$; Peter Gács then showed the theorem; Clemens Lautemann then gave the readable proof we will show – all in 1983
- The result has been further strengthened since, suggesting that BPP strictly smaller, but no relation to any other class we covered so far is known
Theorem 23.2 (Sipser-Gács-Lautemann Theorem): \( \text{BPP} \subseteq \Sigma_2^P \cap \Pi_2^P \)

Proof: Overall proof outline:

- We will show that \( \text{BPP} \subseteq \Sigma_2^P \). This implies \( \text{coBPP} \subseteq \Pi_2^P \), and hence \( \text{BPP} \subseteq \Pi_2^P \) since \( \text{BPP} \) is closed under complement.
- We will show the inclusion for an arbitrary language \( L \in \text{BPP} \).
  - Then there is a PTM \( M \) with the following features:
    - \( M \) runs in time \( p(n) \) for some polynomial \( p \), using \( p(n) \) random bits
    - \( M \) accepts \( L \) with error probability \( \leq 2^{-n} \) (using probability amplification as in Theorem 21.14)
  - We can view the computation of \( M \) as a deterministic polytime computation over an input of length \( n \) and an additional string of \( p(n) \) random bits, as before.
- The key to the proof is the extreme difference between acceptance and rejection:
  - Either \( \geq (1 - 2^{-n})^2 p(n) \) of random vectors \( r \in \{0,1\}^{p(n)} \) lead to acceptance,
  - Or only \( \leq 2^{-n} 2^{p(n)} = 2^{p(n)} - n \) of random vectors \( r \in \{0,1\}^{p(n)} \) lead to acceptance.

\( \{ \text{we want to tell the two situations apart in } \Sigma_2^P \} \)
Theorem 23.2 (Sipser-Gács-Lautemann Theorem): BPP \subseteq \Sigma_2^P \cap \Pi_2^P

Proof: Overall proof outline:

- We will show that BPP \subseteq \Sigma_2^P. This implies coBPP \subseteq \Pi_2^P, and hence BPP \subseteq \Pi_2^P since BPP is closed under complement.
Proving Sipser-Gács-Lautemann (1)

**Theorem 23.2 (Sipser-Gács-Lautemann Theorem):** \( \text{BPP} \subseteq \Sigma_2^P \cap \Pi_2^P \)

- The key to the proof is the extreme difference between acceptance and rejection:
  
  - either \( \geq (1 - 2^{-n})2^{p(n)} \) of random vectors \( r \in \{0, 1\}^{p(n)} \) lead to acceptance,
  - or only \( \leq 2^{-n}2^{p(n)} = 2^{p(n) - n} \) of random vectors \( r \in \{0, 1\}^{p(n)} \) lead to acceptance.

\( \sim \) we want to tell the two situations apart in \( \Sigma_2^P \)
Theorem 23.2 (Sipser-Gács-Lautemann Theorem): $\text{BPP} \subseteq \Sigma_2^p \cap \Pi_2^p$

Proof (continued): Idea for telling apart acceptance and rejection:

- For input $w$, let $S_w \subseteq \{0, 1\}^{p(n)}$ be the set of all random vectors such that, for all $r \in S_w$, $M$ accepts $w$ when using random numbers $r$
**Theorem 23.2 (Sipser-Gács-Lautemann Theorem):** \( \text{BPP} \subseteq \Sigma^p_2 \cap \Pi^p_2 \)

**Proof (continued):** Idea for telling apart acceptance and rejection:

- For input \( w \), let \( S_w \subseteq \{0, 1\}^{p(n)} \) be the set of all random vectors such that, for all \( r \in S_w \), \( M \) accepts \( w \) when using random numbers \( r \).
- \( S_w \in \{0, 1\}^{p(n)} \) is either almost all of \( \{0, 1\}^{p(n)} \), or a tiny fraction thereof.
Theorem 23.2 (Sipser-Gács-Lautemann Theorem): $\text{BPP} \subseteq \Sigma_2^p \cap \Pi_2^p$

Proof (continued): Idea for telling apart acceptance and rejection:

- For input $w$, let $S_w \subseteq \{0, 1\}^{p(n)}$ be the set of all random vectors such that, for all $r \in S_w$, $M$ accepts $w$ when using random numbers $r$.
- $S_w \in \{0, 1\}^{p(n)}$ is either almost all of $\{0, 1\}^{p(n)}$, or a tiny fraction thereof.
- We consider “shifted copies” of $S_w$, created by some uniform bit-flipping $S_w$ vectors:
  - If $S_w$ is large, then polynomially many such copies can cover all of $\{0, 1\}^{p(n)}$.
  - If $S_w$ is small, then polynomially many copies are too small to cover $\{0, 1\}^{p(n)}$. 
Theorem 23.2 (Sipser-Gács-Lautemann Theorem): \( \text{BPP} \subseteq \Sigma_2^P \cap \Pi_2^P \)

Proof (continued): Idea for telling apart acceptance and rejection:

- For input \( w \), let \( S_w \subseteq \{0, 1\}^{p(n)} \) be the set of all random vectors such that, for all \( r \in S_w \), \( M \) accepts \( w \) when using random numbers \( r \)
- \( S_w \in \{0, 1\}^{p(n)} \) is either almost all of \( \{0, 1\}^{p(n)} \), or a tiny fraction thereof
- We consider “shifted copies” of \( S_w \), created by some uniform bit-flipping \( S_w \) vectors:
  - If \( S_w \) is large, then polynomially many such copies can cover all of \( \{0, 1\}^{p(n)} \)
  - If \( S_w \) is small, then polynomially many copies are too small to cover \( \{0, 1\}^{p(n)} \)
- Making a “shifted copy”:
  for some \( u \in \{0, 1\}^{p(n)} \), set \( S_w \oplus u = \{ r \oplus u \mid r \in S_w \} \), where \( \oplus \) is XOR (sum mod 2)
Theorem 23.2 (Sipser-Gács-Lautemmann Theorem): \( \text{BPP} \subseteq \Sigma^P_2 \cap \Pi^P_2 \)

Proof (continued): Idea for telling apart acceptance and rejection:

- For input \( w \), let \( S_w \subseteq \{0, 1\}^{p(n)} \) be the set of all random vectors such that, for all \( r \in S_w \), \( M \) accepts \( w \) when using random numbers \( r \).

  - If \( S_w \) is small, then polynomially many copies are too small to cover \( \{0, 1\}^{p(n)} \).
- Making a “shifted copy”: for some \( u \in \{0, 1\}^{p(n)} \), set \( S_w \oplus u = \{r \oplus u \mid r \in S_w\} \), where \( \oplus \) is XOR (sum mod 2).
- Number of shifted copies: we will use \( k = \left\lceil \frac{p(n)}{n} \right\rceil + 1 \) copies (a polynomial number).
Theorem 23.2 (Sipser-Gács-Lautemmann Theorem): $\text{BPP} \subseteq \Sigma^P_2 \cap \Pi^P_2$

Proof (continued): Idea for telling apart acceptance and rejection:

- For input $w$, let $S_w \subseteq \{0, 1\}^{p(n)}$ be the set of all random vectors such that, for all $r \in S_w$, $M$ accepts $w$ when using random numbers $r$
- $S_w \in \{0, 1\}^{p(n)}$ is either almost all of $\{0, 1\}^{p(n)}$, or a tiny fraction thereof
- We consider “shifted copies” of $S_w$, created by some uniform bit-flipping $S_w$ vectors:
  - If $S_w$ is large, then polynomially many such copies can cover all of $\{0, 1\}^{p(n)}$
  - If $S_w$ is small, then polynomially many copies are too small to cover $\{0, 1\}^{p(n)}$
- Making a “shifted copy”:
  for some $u \in \{0, 1\}^{p(n)}$, set $S_w \oplus u = \{r \oplus u \mid r \in S_w\}$, where $\oplus$ is XOR (sum mod 2)
- Number of shifted copies: we will use $k = \left\lceil \frac{p(n)}{n} \right\rceil + 1$ copies (a polynomial number)

We will show that $k$ random shifts can cover $\{0, 1\}^{p(n)}$ if and only if $S_w$ is “large”.

Markus Krötzsch, 16th Jan 2019 Complexity Theory slide 9 of 23
Theorem 23.2 (Sipser-Gács-Lautemann Theorem): $\text{BPP} \subseteq \Sigma^p_2 \cap \Pi^p_2$

Proof (continued):

**Claim 1:** If $|S_w| \leq 2^{p(n)-n}$, then, for every set of $k = \left\lceil \frac{p(n)}{n} \right\rceil + 1$ vectors $u_1, \ldots, u_k \in \{0, 1\}^{p(n)}$, we have $\bigcup_{i=1}^{k} (S_w \oplus u_i) \subsetneq \{0, 1\}^{p(n)}$. 

| Markus Krötzsch, 16th Jan 2019 Complexity Theory slide 10 of 23 |
Theorem 23.2 (Sipser-Gács-Lautemann Theorem): $\text{BPP} \subseteq \Sigma_2^P \cap \Pi_2^P$

Proof (continued):

Claim 1: If $|S_w| \leq 2^{p(n) - n}$, then, for every set of $k = \left\lceil \frac{p(n)}{n} \right\rceil + 1$ vectors $u_1, \ldots, u_k \in \{0, 1\}^{p(n)}$, we have $\bigcup_{i=1}^{k} (S_w \oplus u_i) \not\subseteq \{0, 1\}^{p(n)}$.

The result follows from the cardinalities of the involved sets:

Using that $|S_w \oplus u_i| = |S_w|$, we obtain:

$$\left| \bigcup_{i=1}^{k} (S_w \oplus u_i) \right| \leq k|S_w| \leq \left( \left\lceil \frac{p(n)}{n} \right\rceil + 1 \right) 2^{p(n) - n} = \left( \left\lceil \frac{p(n)}{n} \right\rceil + 1 \right) 2^{p(n)} = o(2^{p(n)})$$

Therefore the claim holds for sufficiently large $n$. This suffices, since inputs of shorter length can surely be decided in $\Sigma_2^P$ as well.
Proof (continued):

**Claim 2:** If $|S_w| \geq (1 - 2^{-n})2^{p(n)}$, then there is a set of $k = \left\lceil \frac{p(n)}{n} \right\rceil + 1$ vectors $u_1, \ldots, u_k \in \{0, 1\}^{p(n)}$, such that $\bigcup_{i=1}^{k} (S_w \oplus u_i) = \{0, 1\}^{p(n)}$. 

---

Proving Sipser-Gács-Lautemann (4)
Theorem 23.2 (Sipser-Gács-Lautemann Theorem): BPP ⊆ Σ₂^P ∩ Π₂^P

Proof (continued):

Claim 2: If |S_w| ≥ (1 − 2^{-n})2^{p(n)}, then there is a set of \( k = \lceil \frac{p(n)}{n} \rceil + 1 \) vectors \( u_1, \ldots, u_k \in \{0, 1\}^{p(n)} \), such that \( \bigcup_{i=1}^{k} (S_w \oplus u_i) = \{0, 1\}^{p(n)} \).

We argue that, for independently and randomly chosen \( u_1, \ldots, u_k \), we have \( \Pr\left[ \bigcup_{i=1}^{k} (S_w \oplus u_i) = \{0, 1\}^{p(n)} \right] > 0 \). The claim follows from this.
Theorem 23.2 (Sipser-Gács-Lautemann Theorem): BPP $\subseteq \Sigma_2^P \cap \Pi_2^P$

Proof (continued):

Claim 2: If $|S_w| \geq (1 - 2^{-n})2^{p(n)}$, then there is a set of $k = \left\lceil \frac{p(n)}{n} \right\rceil + 1$ vectors $u_1, \ldots, u_k \in \{0, 1\}^{p(n)}$, such that $\bigcup_{i=1}^k (S_w \oplus u_i) = \{0, 1\}^{p(n)}$.

We argue that, for independently and randomly chosen $u_1, \ldots, u_k$, we have

$$\Pr\left[ \bigcup_{i=1}^k (S_w \oplus u_i) = \{0, 1\}^{p(n)} \right] > 0.$$  

The claim follows from this.

For a particular $r \in \{0, 1\}^{p(n)}$, we compute

$$\Pr\left[ r \not\in \bigcup_{i=1}^k (S_w \oplus u_i) \right] \overset{(a)}{=} \prod_{i=1}^k \Pr[r \not\in (S_w \oplus u_i)] \overset{(b)}{=} \prod_{i=1}^k 2^{-n} = 2^{-nk} < 2^{-p(n)}$$

since:

(a) $u_i$ are selected independently;
(b) $\Pr[r \not\in (S_w \oplus u_i)]$. 

Therefore:

$$\Pr\left[ \text{there is } r \in \{0, 1\}^{p(n)} \setminus \bigcup_{i=1}^k (S_w \oplus u_i) \right] < 2^{-p(n)}.$$  

In particular, there is at least one choice of $u_1, \ldots, u_k$ where this event does not occur, i.e., where all $r$ are in $\bigcup_{i=1}^k (S_w \oplus u_i)$. 

Markus Krötzsch, 16th Jan 2019

Complexity Theory
Theorem 23.2 (Sipser-Gács-Lautemann Theorem): \( \text{BPP} \subseteq \Sigma^P_2 \cap \Pi^P_2 \)

Proof (continued):

Claim 2: If \( |S_w| \geq (1 - 2^{-n})2^{p(n)} \), then there is a set of \( k = \left\lceil \frac{p(n)}{n} \right\rceil + 1 \) vectors \( u_1, \ldots, u_k \in \{0, 1\}^{p(n)} \), such that \( \bigcup_{i=1}^{k} (S_w \oplus u_i) = \{0, 1\}^{p(n)} \).

We argue that, for independently and randomly chosen \( u_1, \ldots, u_k \), we have \( \Pr\left[ \bigcup_{i=1}^{k} (S_w \oplus u_i) = \{0, 1\}^{p(n)} \right] > 0 \). The claim follows from this.

For a particular \( r \in \{0, 1\}^{p(n)} \), we compute

\[
\Pr\left[ r \notin \bigcup_{i=1}^{k} (S_w \oplus u_i) \right] = \prod_{i=1}^{k} \Pr\left[ r \notin (S_w \oplus u_i) \right] \leq \prod_{i=1}^{k} 2^{-n} = 2^{-nk} = 2^{-n\left\lceil \frac{p(n)}{n} \right\rceil + 1} < 2^{-p(n)}
\]

since: (a) \( u_i \) are selected independently;
Proof (continued):

Claim 2: If $|S_w| \geq (1 - 2^{-n})2^{p(n)}$, then there is a set of $k = \left\lceil \frac{p(n)}{n} \right\rceil + 1$ vectors $u_1, \ldots, u_k \in \{0, 1\}^{p(n)}$, such that $\bigcup_{i=1}^{k} (S_w \oplus u_i) = \{0, 1\}^{p(n)}$.

We argue that, for independently and randomly chosen $u_1, \ldots, u_k$, we have $\Pr\left[\bigcup_{i=1}^{k} (S_w \oplus u_i) = \{0, 1\}^{p(n)}\right] > 0$. The claim follows from this.

For a particular $r \in \{0, 1\}^{p(n)}$, we compute

$$\Pr\left[r \notin \bigcup_{i=1}^{k} (S_w \oplus u_i)\right] = \prod_{i=1}^{k} \Pr\left[r \notin (S_w \oplus u_i)\right] \leq \prod_{i=1}^{k} 2^{-n} = 2^{-nk} \leq 2^{-n\left\lceil \frac{p(n)}{n} \right\rceil + 1} < 2^{-p(n)}$$

since: (a) $u_i$ are selected independently; (b) $\Pr\left[r \notin (S_w \oplus u_i)\right] = \Pr\left[r \oplus u_i \notin S_w\right] \leq 2^{-n}$
Theorem 23.2 (Sipser-Gács-Lautemann Theorem): \( \text{BPP} \subseteq \Sigma_2^P \cap \Pi_2^P \)

Proof (continued):

**Claim 2:** If \( |S_w| \geq (1 - 2^{-n})2^{p(n)} \), then there is a set of \( k = \left\lceil \frac{p(n)}{n} \right\rceil + 1 \) vectors \( u_1, \ldots, u_k \in \{0, 1\}^{p(n)} \), such that \( \bigcup_{i=1}^{k} (S_w \oplus u_i) = \{0, 1\}^{p(n)} \).

We argue that, for independently and randomly chosen \( u_1, \ldots, u_k \), we have \( \Pr\left[ \bigcup_{i=1}^{k} (S_w \oplus u_i) = \{0, 1\}^{p(n)} \right] > 0 \). The claim follows from this.

For a particular \( r \in \{0, 1\}^{p(n)} \), we compute

\[
\Pr\left[ r \notin \bigcup_{i=1}^{k} (S_w \oplus u_i) \right] = \prod_{i=1}^{k} \Pr\left[ r \notin (S_w \oplus u_i) \right] \leq \prod_{i=1}^{k} 2^{-n} = 2^{-nk} = 2^{-n\left\lceil \frac{p(n)}{n} \right\rceil} < 2^{-p(n)}
\]

since: (a) \( u_i \) are selected independently; (b) \( \Pr\left[ r \notin (S_w \oplus u_i) \right] = \Pr\left[ r \oplus u_i \notin S_w \right] \leq 2^{-n} \)

**Therefore:** \( \Pr\left[ \text{there is } r \in \{0, 1\}^{p(n)} \setminus \bigcup_{i=1}^{k} (S_w \oplus u_i) \right] < 2^{p(n)} \cdot 2^{-p(n)} = 1 \). In particular, there is at least one choice of \( u_1, \ldots, u_n \) where this event does not occur, i.e., where all \( r \) are in \( \bigcup_{i=1}^{k} (S_w \oplus u_i) \).
Theorem 23.2 (Sipser-Gács-Lautemann Theorem): \( \text{BPP} \subseteq \Sigma^P_2 \cap \Pi^P_2 \)

Proof (continued): In summary, we have shown:

- If \( S_w \) is “small,” then there are no vectors \( u_1, \ldots, u_k \) such that \( \bigcup_{i=1}^{k} (S_w \oplus u_i) = \{0, 1\}^{p(n)} \)
- If \( S_w \) is “large,” then there are vectors \( u_1, \ldots, u_k \) such that \( \bigcup_{i=1}^{k} (S_w \oplus u_i) = \{0, 1\}^{p(n)} \)

Hence, we can check the acceptance of \( M \) by computing if the following holds true:

\[
\exists u_1, \ldots, u_k. \forall r \in \{0, 1\}^{p(n)}. r \in \bigcup_{i=1}^{k} (S_w \oplus u_i)
\]

Using the DTM version of PTMs, this becomes:

\[
\exists u_1, \ldots, u_k. \forall r \in \{0, 1\}^{p(n)}. k \bigvee_{i=1}^{k} M \text{ accepts } w \text{ for random vector } r \oplus u_i
\]

This is a \( \Sigma^P_2 \) computation. \( \square \)
Theorem 23.2 (Sipser-Gács-Lautemann Theorem): \( \text{BPP} \subseteq \Sigma^P_2 \cap \Pi^P_2 \)

Proof (continued): In summary, we have shown:

- If \( S_w \) is “small,” then there are no vectors \( u_1, \ldots, u_k \) such that \( \bigcup_{i=1}^{k} (S_w \oplus u_i) = \{0, 1\}^{p(n)} \)
- If \( S_w \) is “large,” then there are vectors \( u_1, \ldots, u_k \) such that \( \bigcup_{i=1}^{k} (S_w \oplus u_i) = \{0, 1\}^{p(n)} \)

Hence, we can check the acceptance of \( M \) by computing if the following holds true:

\[
\exists u_1, \ldots, u_k. \forall r \in \{0, 1\}^{p(n)} \cdot r \in \bigcup_{i=1}^{k} (S_w \oplus u_i)
\]

Using the DTM version of PTMs, this becomes:

\[
\exists u_1, \ldots, u_k. \forall r \in \{0, 1\}^{p(n)} \cdot \bigvee_{i=1}^{k} M \text{ accepts } w \text{ for random vector } r \oplus u_i
\]
Theorem 23.2 (Sipser-Gács-Lautemann Theorem): \( \text{BPP} \subseteq \Sigma^P_2 \cap \Pi^P_2 \)

Proof (continued): In summary, we have shown:

- If \( S_w \) is “small,” then there are no vectors \( u_1, \ldots, u_k \) such that \( \bigcup_{i=1}^{k} (S_w \oplus u_i) = \{0, 1\}^{p(n)} \)
- If \( S_w \) is “large,” then there are vectors \( u_1, \ldots, u_k \) such that \( \bigcup_{i=1}^{k} (S_w \oplus u_i) = \{0, 1\}^{p(n)} \)

Hence, we can check the acceptance of \( M \) by computing if the following holds true:

\[

\]

Using the DTM version of PTMs, this becomes:

\[
\exists u_1, \ldots, u_k. \forall r \in \{0, 1\}^{p(n)}. \bigvee_{i=1}^{k} M \text{ accepts } w \text{ for random vector } r \oplus u_i
\]

This is a \( \Sigma^P_2 \) computation. \( \square \)
The **Time Hierarchy Theorems** for deterministic and non-deterministic Turing machines show that, when given (sufficiently) more time, such TMs can solve more problems. In particular:

- $P \neq \text{ExpTime}$
- $NP \neq \text{NExpTime}$

The proofs were based on **diagonalisation arguments** that enabled TMs with more time to deliberately differ from all TMs with less time.
Hierarchical Theorems for BPP

The Time Hierarchy Theorems for deterministic and non-deterministic Turing machines show that, when given (sufficiently) more time, such TMs can solve more problems. In particular:

- \( P \neq \text{ExpTime} \)
- \( \text{NP} \neq \text{NExpTime} \)

The proofs were based on diagonalisation arguments that enabled TMs with more time to deliberately differ from all TMs with less time.

Unfortunately, no such arguments are known for BPP:

- The difficulty of applying diagonalisation arguments is related to the semantic definition of BPP.
- Currently, we don’t even know if \( \text{BPP} \neq \text{NExpTime} \)!
Relationship of BPP and P

We know $P \subseteq BPP \subseteq PP \subseteq PSpace$ but not even if $BPP \neq NExpTime$.

However, most experts expect that . . .
Relationship of BPP and P

We know $P \subseteq BPP \subseteq PP \subseteq PSpace$ but not even if $BPP \neq NExpTime$.

However, most experts expect that . . .

BPP is equal to P!
Relationship of BPP and P

We know $P \subseteq BPP \subseteq PP \subseteq PSpace$ but not even if $BPP \neq NExpTime$.

However, most experts expect that . . .

**BPP is equal to P!**

- Many BPP algorithms have been de-randomised successfully
- $BPP = P$ is equivalent to the existence of strong pseudo-random number generators, which many experts consider likely
Further probabilistic classes
Types of errors

We have defined BPP by restricting the probability of error to \( \leq \frac{1}{3} \).

However, there are two types of errors:

- **False positives**: the PTM accepts a word that is not in the language
- **False negatives**: the PTM rejects a word that is in the language

Common BPP algorithms can often avoid one of these errors:

**Example 23.3:** Our previous algorithm for polynomial identity testing aimed to decide \( \text{ZEROP} \). For inputs \( w \in \text{ZEROP} \), the algorithm accepted with probability 1 (no false negatives). Uncertainty only occurred for inputs \( w \notin \text{ZEROP} \) (false positives were possible, though unlikely).
Randomised Polynomial Time

Excluding false positives/negatives from BPP leads to classes with one-sided error:

**Definition 23.4:** A language $L$ is in Randomised Polynomial Time (RP) if there is a PTM $M$ such that:
- there is a polynomial function $f$ such that $M$ will always halt after $f(|w|)$ steps on all input words $w$,
- if $w \in L$, then $\Pr[M \text{ accepts } w] \geq \frac{2}{3}$,
- if $w \notin L$, then $\Pr[M \text{ accepts } w] = 0$.

**Definition 23.5:** A language $L$ is in coRP if its complement is in RP, i.e., if there is a polynomially time-bounded PTM $M$ such that:
- if $w \in L$, then $\Pr[M \text{ accepts } w] = 1$,
- if $w \notin L$, then $\Pr[M \text{ accepts } w] \leq \frac{1}{3}$.

**Example 23.6:** $\text{ZeroP} \in \text{coRP}$.
It is clear from the definitions that $\text{RP} \subseteq \text{BPP}$ and $\text{coRP} \subseteq \text{BPP}$.

Hence, we can apply Theorem 21.14 to amplify the output probability.
Probability amplification for RP and coRP

It is clear from the definitions that $\text{RP} \subseteq \text{BPP}$ and $\text{coRP} \subseteq \text{BPP}$.

Hence, we can apply Theorem 21.14 to amplify the output probability.

However, the situation for one-sided error classes is actually much simpler:

**Theorem 23.7:** Consider a language $L$ and a polynomially time-bounded PTM $M$ for which there is a constant $c > 0$ such that, for every word $w \in \Sigma^*$,

- if $w \in L$ then $\Pr [M \text{ accepts } w] \geq |w|^{-c}$
- if $w \notin L$ then $\Pr [M \text{ accepts } w] = 0$

Then, for every constant $d > 0$, there is a polynomially time-bounded PTM $M'$ such that

- if $w \in L$ then $\Pr [M' \text{ accepts } w] \geq 1 - 2^{-|w|^d}$
- if $w \notin L$ then $\Pr [M' \text{ accepts } w] = 0$.

**Proof:** Much simpler than for BPP (exercise).
The asymmetric acceptance conditions of RP reminds us of NP, since already “some” accepting runs are enough to prove acceptance.

\[ \text{Theorem 23.8:} \quad \text{RP} \subseteq \text{NP} \]
\[ \text{Proof:} \quad \text{If } M \text{ satisfies the RP acceptance conditions for } L, \text{ then } M \text{ can be considered as an NTM that accepts } L \text{ with respect to the usual non-deterministic acceptance conditions. Indeed, } M \text{ has an accepting run on input } |w| \text{ if and only if } w \in L. \quad \square \]

Similarly, we find coRP $\subseteq$ coNP.

Recall: While RP $\subseteq$ BPP, we do not know whether BPP $\subseteq$ NP.
The asymmetric acceptance conditions of RP reminds us of NP, since already “some” accepting runs are enough to prove acceptance.

Indeed, we get:

**Theorem 23.8:** $\text{RP} \subseteq \text{NP}$

**Proof:** If $M$ satisfies the RP acceptance conditions for $L$, then $M$ can be considered as an NTM that accepts $L$ with respect to the usual non-deterministic acceptance conditions. Indeed, $M$ has an accepting run on input $|w|$ if and only if $w \in L$. $\Box$

Similarly, we find $\text{coRP} \subseteq \text{coNP}$.

**Recall:** While $\text{RP} \subseteq \text{BPP}$, we do not know whether $\text{BPP} \subseteq \text{NP}$. 
Zero-sided error

Instead of admitting a possibly false answer (positive or negative), one can also require the correct answer while making some concessions on runtime:

**Definition 23.9:** A PTM $\mathcal{M}$ has **expected runtime** $f : \mathbb{N} \rightarrow \mathbb{R}$ if, for any input $w$, the expectation $E[T_w]$ of the number $T_w$ of steps taken by $\mathcal{M}$ on input $w$ is $T_w \leq f(|w|)$.

**ZPP** is the class of all languages for which there is a PTM $\mathcal{M}$ that

- returns the correct answer whenever it halts,
- has expected runtime $f$ for some polynomial function $f$.

ZPP is for **zero-error probabilistic polynomial time**.
Zero-sided error

Instead of admitting a possibly false answer (positive or negative), one can also require the correct answer while making some concessions on runtime:

**Definition 23.9:** A PTM $\mathcal{M}$ has expected runtime $f : \mathbb{N} \rightarrow \mathbb{R}$ if, for any input $w$, the expectation $E[T_w]$ of the number $T_w$ of steps taken by $\mathcal{M}$ on input $w$ is $T_w \leq f(|w|)$.

**ZPP** is the class of all languages for which there is a PTM $\mathcal{M}$ that
- returns the correct answer whenever it halts,
- has expected runtime $f$ for some polynomial function $f$.

**ZPP** is for zero-error probabilistic polynomial time.

**Note:** In general, algorithms that produce correct results while giving only probabilistic guarantees on resource usage are called Las Vegas algorithms, as opposed to Monte Carlo algorithms, which have guaranteed resource bounds but probabilistic correctness (as in the case of BPP).
Zero-sided vs. one-sided error

In spite of the different approaches of expected error vs. expected runtime, we find a close relation between ZPP, RP, and coRP:

**Theorem 23.10:** $\text{ZPP} = \text{RP} \cap \text{coRP}$
Zero-sided vs. one-sided error

In spite of the different approaches of expected error vs. expected runtime, we find a close relation between ZPP, RP, and coRP:

**Theorem 23.10:** $\text{ZPP} = \text{RP} \cap \text{coRP}$

**Proof:** $\text{ZPP} \subseteq \text{RP}$:
Zero-sided vs. one-sided error

In spite of the different approaches of expected error vs. expected runtime, we find a close relation between ZPP, RP, and coRP:

**Theorem 23.10:** \( \text{ZPP} = \text{RP} \cap \text{coRP} \)

**Proof:** \( \text{ZPP} \subseteq \text{RP} \): Given a ZPP algorithm \( M \), construct an RP algorithm by running \( M \) for three times the expected (polynomial) runtime \( t \). If it stops, return the same answer; if it times out, reject.
Zero-sided vs. one-sided error

In spite of the different approaches of expected error vs. expected runtime, we find a close relation between ZPP, RP, and coRP:

**Theorem 23.10:** $\text{ZPP} = \text{RP} \cap \text{coRP}$

**Proof:** ZPP $\subseteq$ RP: Given a ZPP algorithm $\cal{M}$, construct an RP algorithm by running $\cal{M}$ for three times the expected (polynomial) runtime $t$. If it stops, return the same answer; if it times out, reject.

- For any random variable $X$ and $c > 0$, Markov’s inequality implies:
  $$\Pr[X \geq cE[X]] \leq \frac{E[X]}{cE[X]} = \frac{1}{c}$$
Zero-sided vs. one-sided error

In spite of the different approaches of expected error vs. expected runtime, we find a close relation between ZPP, RP, and coRP:

**Theorem 23.10:** \( \text{ZPP} = \text{RP} \cap \text{coRP} \)

**Proof:** \( \text{ZPP} \subseteq \text{RP} \): Given a ZPP algorithm \( M \), construct an RP algorithm by running \( M \) for three times the expected (polynomial) runtime \( t \). If it stops, return the same answer; if it times out, reject.

- For any random variable \( X \) and \( c > 0 \), Markov’s inequality implies:
  \[ \Pr[X \geq cE[X]] \leq \frac{E[X]}{cE[X]} = \frac{1}{c} \]
- Hence the probability of \( M \) running for \( \geq 3t \) is \( \leq \frac{1}{3} \)
Zero-sided vs. one-sided error

In spite of the different approaches of expected error vs. expected runtime, we find a close relation between ZPP, RP, and coRP:

**Theorem 23.10:** \( \text{ZPP} = \text{RP} \cap \text{coRP} \)

**Proof:** \( \text{ZPP} \subseteq \text{RP} \): Given a ZPP algorithm \( \mathcal{M} \), construct an RP algorithm by running \( \mathcal{M} \) for three times the expected (polynomial) runtime \( t \). If it stops, return the same answer; if it times out, reject.

- For any random variable \( X \) and \( c > 0 \), Markov’s inequality implies:
  \[
  \Pr [X \geq cE[X]] \leq \frac{E[X]}{cE[X]} = \frac{1}{c}
  \]
- Hence the probability of \( \mathcal{M} \) running for \( \geq 3t \) is \( \leq \frac{1}{3} \)
- Therefore, the probability of a false negative (due to a timeout) is \( \leq \frac{1}{3} \)
Zero-sided vs. one-sided error

In spite of the different approaches of expected error vs. expected runtime, we find a close relation between ZPP, RP, and coRP:

**Theorem 23.10:** ZPP = RP ∩ coRP

**Proof:** ZPP ⊆ RP: Given a ZPP algorithm $M$, construct an RP algorithm by running $M$ for three times the expected (polynomial) runtime $t$. If it stops, return the same answer; if it times out, reject.

- For any random variable $X$ and $c > 0$, Markov’s inequality implies:
  \[
  \Pr [X \geq cE[X]] \leq \frac{E[X]}{cE[X]} = \frac{1}{c}
  \]
- Hence the probability of $M$ running for $\geq 3t$ is $\leq \frac{1}{3}$
- Therefore, the probability of a false negative (due to a timeout) is $\leq \frac{1}{3}$

ZPP ⊆ coRP is dual; we just have to accept after timeout.
Zero-sided vs. one-sided error

In spite of the different approaches of expected error vs. expected runtime, we find a close relation between ZPP, RP, and coRP:

**Theorem 23.10:** $\text{ZPP} = \text{RP} \cap \text{coRP}$

**Proof:** $\text{ZPP} \supseteq \text{RP} \cap \text{coRP}$: Assume we have an RP algorithm $\mathcal{A}$ and a coRP algorithm $\mathcal{B}$ for the same language $L$. 

- If $\mathcal{A}$ rejects, reject.
- If $\mathcal{B}$ accepts, accept.
- If $\mathcal{A}$ accepts and $\mathcal{B}$ rejects, repeat the experiment.

Since RP has no false positives and coRP has no false negatives, this can only return the correct answer. The probability of repetition is $\leq \frac{1}{3}$, since it requires one of the algorithms to be in error. Hence the probability of $k$ repetitions is $\leq 3^{-k}$, for an expected runtime of $\leq \sum_{k \geq 0} (k+1)p^3_k$, where $p$ is the combined (polynomial) runtime of $\mathcal{A}$ and $\mathcal{B}$. This is polynomial. □
Zero-sided vs. one-sided error

In spite of the different approaches of expected error vs. expected runtime, we find a close relation between ZPP, RP, and coRP:

**Theorem 23.10:** \( \text{ZPP} = \text{RP} \cap \text{coRP} \)

**Proof:** \( \text{ZPP} \supseteq \text{RP} \cap \text{coRP} \): Assume we have an RP algorithm \( A \) and a coRP algorithm \( B \) for the same language \( L \). To obtain a ZPP algorithm, we run \( A \) and \( B \) on input \( w \):

- If \( A \) rejects, reject
- If \( B \) accepts, accept
- If \( A \) accepts and \( B \) rejects, repeat the experiment.

Since RP has no false positives and coRP has no false negatives, this can only return the correct answer. The probability of repetition is \( \leq \frac{1}{3} \), since it requires one of the algorithms to be in error. Hence the probability of \( k \) repetitions is \( \leq 3^{-k} \), for an expected runtime of \( \leq \sum_{k \geq 0} (k+1)p^{3^k} \), where \( p \) is the combined (polynomial) runtime of \( A \) and \( B \). This is polynomial. \( \square \)
Zero-sided vs. one-sided error

In spite of the different approaches of expected error vs. expected runtime, we find a close relation between ZPP, RP, and coRP:

**Theorem 23.10:** $\text{ZPP} = \text{RP} \cap \text{coRP}$

**Proof:** $\text{ZPP} \supseteq \text{RP} \cap \text{coRP}$: Assume we have an RP algorithm $A$ and a coRP algorithm $B$ for the same language $L$. To obtain a ZPP algorithm, we run $A$ and $B$ on input $w$:

- If $A$ rejects, reject
- If $B$ accepts, accept
- If $A$ accepts and $B$ rejects, repeat the experiment.

Since RP has no false positives and coRP has no false negatives, this can only return the correct answer.
Zero-sided vs. one-sided error

In spite of the different approaches of expected error vs. expected runtime, we find a close relation between ZPP, RP, and coRP:

**Theorem 23.10:** $ZPP = RP \cap coRP$

**Proof:** $ZPP \supseteq RP \cap coRP$: Assume we have an RP algorithm $A$ and a coRP algorithm $B$ for the same language $L$. To obtain a ZPP algorithm, we run $A$ and $B$ on input $w$:

- If $A$ rejects, reject
- If $B$ accepts, accept
- If $A$ accepts and $B$ rejects, repeat the experiment.

Since RP has no false positives and coRP has no false negatives, this can only return the correct correct answer.

The probability of repetition is $\leq \frac{1}{3}$, since it requires one of the algorithms to be in error.
Zero-sided vs. one-sided error

In spite of the different approaches of expected error vs. expected runtime, we find a close relation between ZPP, RP, and coRP:

**Theorem 23.10:** $\text{ZPP} = \text{RP} \cap \text{coRP}$

**Proof:** $\text{ZPP} \supseteq \text{RP} \cap \text{coRP}$: Assume we have an RP algorithm $A$ and a coRP algorithm $B$ for the same language $L$. To obtain a ZPP algorithm, we run $A$ and $B$ on input $w$:

- If $A$ rejects, reject
- If $B$ accepts, accept
- If $A$ accepts and $B$ rejects, repeat the experiment.

Since RP has no false positives and coRP has no false negatives, this can only return the correct answer.

The probability of repetition is $\leq \frac{1}{3}$, since it requires one of the algorithms to be in error.

Hence the probability of $k$ repetitions is $\leq 3^{-k}$, for an expected runtime of $\leq \sum_{k \geq 0} \frac{(k+1)p}{3^k}$, where $p$ is the combined (polynomial) runtime of $A$ and $B$. This is polynomial. □
Summary and Outlook

Complexity relationships: see board (or make your own drawing)

Probabilistic classes with ones-sided error – RP and coRP – are common.

ZPP defines random computations with zero-sided error, but probabilistic runtime.

Many experts believe that

\[ P = \text{ZPP} = \text{RP} = \text{coRP} = \text{BPP} \subseteq \text{PP} \]
