KNOWLEDGE GRAPHS

Lecture 2: Encoding Graphs with RDF

Markus Krötzsch
Knowledge-Based Systems

TU Dresden, 23th Oct 2018
Encoding Graphs

We have seen that graphs can be encoded in several ways:

- **Adjacency matrix** (and variants)
- **Adjacency list** (and variants)
- **Other derived representations**
We have seen that graphs can be encoded in several ways:

• Adjacency matrix (and variants)
• Adjacency list (and variants)
• Other derived representations

This is enough to store and manipulate graphs in software, but it is not enough to exchange graphs across applications.
Encoding Graphs

We have seen that graphs can be encoded in several ways:

- Adjacency matrix (and variants)
- Adjacency list (and variants)
- Other derived representations

This is enough to store and manipulate graphs in software, but it is not enough to exchange graphs across applications.

**Open questions:**

- What kind(s) of graph do we want to exchange?
- How are vertices given (numbers? strings? specific ids? . . . )?
- Are edge labels supported and what are they?
- Can the graph include values of data types (integer? float? string? times? . . . )?
- How exactly are these things encoded in bytes in a file?
The Resource Description Framework

RDF is a W3C\textsuperscript{1} standard for exchanging graphs

- First proposed in 1999
- Updated in 2004 (RDF 1.0) and in 2014 (RDF 1.1)
- Originally built for Web data exchange
- Meanwhile used in many graph database applications
- Supported by many other W3C standards (RDFa, SPARQL, OWL, SHACL, \ldots)

\textsuperscript{1}World Wide Web Consortium
RDF is a W3Cstandard for exchanging graphs

- First proposed in 1999
- Updated in 2004 (RDF 1.0) and in 2014 (RDF 1.1)
- Originally built for Web data exchange
- Meanwhile used in many graph database applications
- Supported by many other W3C standards (RDFa, SPARQL, OWL, SHACL, …)

In this lecture: focus on graph representation features of RDF 1.1
RDF is a W3C\textsuperscript{1} standard for exchanging graphs

Graphs in RDF

RDF allows us to specify graphs that are:

- **directed** (edges have a source and a target)
- **edge-labelled** (edges have one label)
- a restricted form of **multi-graphs** (multiple edges can exist between same vertices, but only if they have different labels)
Graphs in RDF

RDF allows us to specify graphs that are:

- directed (edges have a source and a target)
- edge-labelled (edges have one label)
- a restricted form of multi-graphs (multiple edges can exist between same vertices, but only if they have different labels)

Example of such a graph:

- Melitta Bentz
- Dresden
- coffee filter
- Melitta
- company
- inventor
- named after
- born in
- founder
- instance of
- produces
- invention

Markus Krötzsch, 23th Oct 2018
Identifiers in RDF

How should we refer to vertices? What kind of labels are allowed?

Definition 2.1:
A Uniform Resource Identifier (URI) is a sequence (string) of a subset of ASCII characters as defined in RFC 3986 (link). Every (absolute) URI consists of a string that defines a scheme, followed by a colon (:) and another sequence of characters specifying an authority, path, query, and fragment, where all parts other than the path are optional.

A International Resource Identifier (IRI) is a generalised form of URI that allows for an expanded range of Unicode glyphs in part of its syntax.

Example 2.2:
URLs are a well-known form of URI, for example:
```
https://example.org/some/page?get=something&lang=en#results
```

Convention:
We ignore the differences between URIs and IRIs in this course. (The lecturer will often say “URI” when he should say “IRI.” Please ignore.)
Identifiers in RDF

How should we refer to vertices? What kind of labels are allowed?

**Definition 2.1:** A Uniform Resource Identifier (URI) is a sequence (string) of a subset of ASCII characters as defined in RFC 3986 (link). Every (absolute) URI consists of a string that defines a scheme, followed by a colon (:) and another sequence of characters specifying an authority, path, query, and fragment, where all parts other than the path are optional.

A International Resource Identifier (IRI) is a generalised form of URI that allows for an expanded range of Unicode glyphs in part of its syntax.
How should we refer to vertices? What kind of labels are allowed?

**Definition 2.1:** A Uniform Resource Identifier (URI) is a sequence (string) of a subset of ASCII characters as defined in RFC 3986 (link). Every (absolute) URI consists of a string that defines a **scheme**, followed by a colon (:) and another sequence of characters specifying an **authority**, **path**, **query**, and **fragment**, where all parts other than the path are optional.

A **International Resource Identifier** (IRI) is a generalised form of URI that allows for an expanded range of Unicode glyphs in part of its syntax.

**Example 2.2:** URLs are a well-known form of URI, for example:

```
https://example.org/some/page?get=something&lang=en #results
```

scheme authority path query fragment
Identifiers in RDF

How should we refer to vertices? What kind of labels are allowed?

**Definition 2.1:** A Uniform Resource Identifier (URI) is a sequence (string) of a subset of ASCII characters as defined in RFC 3986 (link). Every (absolute) URI consists of a string that defines a scheme, followed by a colon (:) and another sequence of characters specifying an authority, path, query, and fragment, where all parts other than the path are optional.

A International Resource Identifier (IRI) is a generalised form of URI that allows for an expanded range of Unicode glyphs in part of its syntax.

**Example 2.2:** URLs are a well-known form of URI, for example:

```
https://example.org/some/page?get=something&lang=en#results
```

scheme  authority  path  query  fragment

**Convention:** We ignore the differences between URIs and IRIs in this course.

(The lecturer will often say “URI” when he should say “IRI.” Please ignore.)
The widely used term Uniform Resource Locator (URL) is an informal way to refer to URIs that specify the location of a digital document. Not all URIs support this.

**Example 2.3:** Many URI schemes have been defined. Examples include

- http, https, ftp for transferring data using various protocols
- mailto for emails (=path)
- irc for specifying IRC channels
- file for referring to locations on some file system
- urn for naming resources without defining a protocol or resolution mechanism; used, e.g., for ISBNs

Registered schemes usually provide some additional syntax requirements, access protocols, and resolution mechanisms, and they often relate to a registration procedure based on some authority.
IRIs in RDF

RDF uses IRIs in two ways:

- IRIs define resources that appear as vertices in the graph
- IRIs are used as property labels

Example of such a graph:

https://example.org/Melitta-Bentz
https://www.dresden.de/#uri
https://example.org/Melitta
https://example.org/company
https://example.org/coffee-filter
https://example.org/founder
https://example.org/named-after
https://example.org/born-in
https://example.org/invention
https://example.org/inventor
https://example.org/produces
http://www.w3.org/1999/02/22-rdf-syntax-ns#type

Note: It is not always obvious what an IRI is supposed to refer to, and many IRIs may refer to the same thing – we cannot assume that all RDF data in the world is integrated.
IRIs in RDF

RDF uses IRIs in two ways:

- IRIs define resources that appear as vertices in the graph
- IRIs are used as property labels

Example of such a graph:

Note: It is not always obvious what an IRI is supposed to refer to, and many IRIs may refer to the same thing – we cannot assume that all RDF data in the world is integrated.
Which IRIs to use?

Where do the IRIs that we use in graphs come from?

- They can be newly created for an application to avoid confusion with resources in other graphs.
- They can be IRIs that are already in common use to support information integration and re-use across graphs.

Guidelines for creating new IRIs:

1. Check if you could re-use an existing IRI to avoid duplication if feasible.
2. Use http(s) IRIs to take advantage of useful protocols, registries, and resolution mechanisms.
3. Create new IRIs based on domains that you own to clearly own them and avoid danger of clashing with other people’s IRIs.
4. Don’t use URLs of existing web pages, unless you want to store data about pages to avoid confusion between pages and more abstract resources.
5. Make your IRIs return some useful content via http(s) to help others to get information about your resources.
Which IRIs to use?

Where do the IRIs that we use in graphs come from?

- They can be newly created for an application
  - avoid confusion with resources in other graphs
- They can be IRIs that are already in common use
  - support information integration and re-use across graphs

Guidelines for creating new IRIs:

1. Check if you could re-use an existing IRI
   - avoid duplication if feasible
2. Use http(s) IRIs
   - useful protocols, registries, resolution mechanisms
3. Create new IRIs based on domains that you own
   - clear ownership; no danger of clashing with other peoples’ IRIs
4. Don’t use URLs of existing web pages, unless you want to store data about pages
   - avoid confusion between pages and more abstract resources
5. Make your IRIs return some useful content via http(s)
   - helps others to get information about your resources
Which IRIs to use?

Where do the IRIs that we use in graphs come from?

- They can be newly created for an application
  \(\mapsto\) avoid confusion with resources in other graphs
- They can be IRIs that are already in common use
  \(\mapsto\) support information integration and re-use across graphs

Guidelines for creating new IRIs:

1. Check if you could re-use an existing IRI \(\mapsto\) avoid duplication if feasible
2. Use http(s) IRIs \(\mapsto\) useful protocols, registries, resolution mechanisms
3. Create new IRIs based on domains that you own \(\mapsto\) clear ownership; no danger of clashing with other peoples’ IRIs
4. Don’t use URLs of existing web pages, unless you want to store data about pages \(\mapsto\) avoid confusion between pages and more abstract resources
5. Make your IRIs return some useful content via http(s) \(\mapsto\) helps others to get information about your resources
Why IRIs?

**URIs may seem a bit complicated**

- They look a bit technical and complex
- They are hard to display or draw in a graph
- The guidelines just given may seem quite demanding to newcomers
Why IRIs?

**URIs may seem a bit complicated**

- They look a bit technical and complex
- They are hard to display or draw in a graph
- The guidelines just given may seem quite demanding to newcomers

**However, it’s not that hard:**

- RDF can work with any form of IRI (most tools would probably accept any Latin letter string with a colon inside!)
- The guidelines help sharing graphs across applications – a strength of RDF
- Internet domain name registration is a very simple way to define ownership in a global data space
- IRIs should not be shown to users (we will introduce human-readable labels soon)
Excursion: Resolvable IRIs

We asked for IRIs that are different from URLs of Web pages while at the same time returning some useful content via http(s).

How is this possible?

1. Use fragments. IRIs with fragments are different from the IRIs (URLs) without the fragment, but resolving them will return the content of this fragment-less IRI.

2. Use HTTP redirects. Web servers can be configured to transparently redirect one URL to another; for IRIs it is common to use HTTP response codes 302 (temporary redirect) or 303 (see other).

Example 2.4: The Wikidata IRI http://www.wikidata.org/entity/Q5 redirects permanently (301) to https://www.wikidata.org/entity/Q5, which redirects (303) to https://www.wikidata.org/wiki/Special:EntityData/Q5, which by default redirects (303) to a JSON document https://www.wikidata.org/wiki/Special:EntityData/Q5.json.

Real-world server configurations can be complicated.
Excursion: Resolvable IRIs

We asked for IRIs that are different from URLs of Web pages while at the same time returning some useful content via http(s).

How is this possible?

1. **Use fragments.** IRIs with fragments are different from the IRIs (URLs) without the fragment, but resolving them will return the content of this fragment-less IRI.

   **Example 2.4:** RDF uses some own IRIs for special purposes, e.g., http://www.w3.org/1999/02/22-rdf-syntax-ns#type for denoting the relation between resources and their type (class). This resolves to http://www.w3.org/1999/02/22-rdf-syntax-ns but is not the identifier of this document.

2. **Use HTTP redirects.** Web servers can be configured to transparently redirect one URL to another; for IRIs it is common to use HTTP response codes 302 (temporary redirect) or 303 (see other).

   **Example 2.5:** The Wikidata IRI http://www.wikidata.org/entity/Q5 redirects permanently (301) to https://www.wikidata.org/entity/Q5, which redirects (303) to https://www.wikidata.org/wiki/Special:EntityData/Q5, which by default redirects (303) to a JSON document https://www.wikidata.org/wiki/Special:EntityData/Q5.json.

Real-world server configurations can be complicated.
Excursion: Resolvable IRIs

We asked for IRIs that are different from URLs of Web pages while at the same time returning some useful content via http(s).

How is this possible?

(1) **Use fragments.** IRIs with fragments are different from the IRIs (URLs) without the fragment, but resolving them will return the content of this fragment-less IRI.

(2) **Use HTTP redirects.** Web servers can be configured to transparently redirect one URL to another; for IRIs it is common to use HTTP response codes 302 (temporary redirect) or 303 (see other)

**Example 2.4:** The Wikidata IRI http://www.wikidata.org/entity/Q5 redirects permanently (301) to https://www.wikidata.org/entity/Q5, which redirects (303) to https://www.wikidata.org/wiki/Special:EntityData/Q5, which by default redirects (303) to a JSON document https://www.wikidata.org/wiki/Special:EntityData/Q5.json.

Real-world server configurations can be complicated.
The redirect mechanism has another useful application: Web servers (and the software they run) can dynamically decide where to redirect to.

**Content negotiation** is the practice of offering several documents under the same URL by redirecting to the version that is most suitable for the request of a client. The HTTP protocol allows clients and servers to exchange extra information with their request that can be used to state preferences.

**Example 2.5:** The `Accept` header is commonly used by clients to select preferred result formats for a request. For example, the command

```
```

makes Wikidata return RDF data in Turtle format rather than JSON.
IRIs can represent anything, but data values (numbers, strings, times, …) should not be represented by IRIs!
IRIs can represent anything, but data values (numbers, strings, times, . . . ) should not be represented by IRIs!

Why not use IRIs here too?
Data values

IRIs can represent anything, but data values (numbers, strings, times, …) should not be represented by IRIs!

Why not use IRIs here too?

1. Data values are the same everywhere $\rightsquigarrow$ no use in application-specific IRIs
IRIs can represent anything, but **data values** (numbers, strings, times, . . . ) should not be represented by IRIs!

**Why not use IRIs here too?**

1. Data values are the same everywhere $\sim$ no use in application-specific IRIs
2. Many RDF-based applications need a built-in understanding of data values (e.g., for sorting content)
Data values

IRIs can represent anything, but data values (numbers, strings, times, . . . ) should not be represented by IRIs!

Why not use IRIs here too?

(1) Data values are the same everywhere $\sim$ no use in application-specific IRIs

(2) Many RDF-based applications need a built-in understanding of data values (e.g., for sorting content)

(3) Data values are usually more “interpreted” than IRIs.

---

**Example 2.6:** Using a hypothetical scheme “integer,” the IRIs `integer:42` and `integer:+42` would be different, but intuitively they should represent the same number.
Encoding data values

- Data values in RDF are written in the format "lexical value"^^datatype-IRI
- They are drawn as rectangular nodes in graphs
Encoding data values

- Data values in RDF are written in the format "lexical value"^^datatype-IRI
- They are drawn as rectangular nodes in graphs

Example graph with data values:

```
https://www.dresden.de/#uri
https://example.org/Melitta-Bentz
"547172"^^xsd:int
"Melitta Bentz"^^xsd:string
"1873-01-31"^^xsd:date
```

RDF supports many different datatypes, most of which are based on XML Schema ("xsd")
**Definition 2.7:** A **datatype** in RDF is specified by the following components:

- The **value space** is the set of possible values of this type.
- The **lexical space** is a set of strings\(^a\) that can be used to denote values of this type.
- The **lexical-to-value mapping** is a function that maps each string from the lexical space to an element of the value space.

\(^a\)RDF is based on Unicode strings, but this is inessential here.

Datatypes for RDF must be identified by IRIs (known to software that supports them).
RDF datatypes

**Definition 2.7:** A datatype in RDF is specified by the following components:

- The **value space** is the set of possible values of this type.
- The **lexical space** is a set of strings\(^a\) that can be used to denote values of this type.
- The **lexical-to-value mapping** is a function that maps each string from the lexical space to an element of the value space.

\(^a\)RDF is based on Unicode strings, but this is inessential here.

Datatypes for RDF must be identified by IRIs (known to software that supports them).

**Example 2.8:** The W3C standard XML Schema defines the datatype **integer**, identified by the IRI `http://www.w3.org/2001/XMLSchema#integer`, has the value space of all integer numbers (of arbitrarily large absolute value), the lexical space of finite-length strings of decimal digits (0–9) with an optional leading sign (− or +), and the expected lexical-to-value mapping.
Important datatypes in RDF

Many standard datatypes are defined by XML Schema (currently in version 1.1 of 2012):

<table>
<thead>
<tr>
<th>Name</th>
<th>Value space</th>
<th>Lexical space</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>XML-defined subset of Unicode strings</td>
<td>Value space (mapping is identity)</td>
</tr>
<tr>
<td>boolean</td>
<td>The set {true, false}</td>
<td>The set {true, false, 1, 0}</td>
</tr>
<tr>
<td>decimal</td>
<td>Arbitrary-precision decimal numbers</td>
<td>Sequences of decimal digits, optionally signed and with one .</td>
</tr>
<tr>
<td>integer</td>
<td>Arbitrary integer numbers</td>
<td>Like decimal but without .</td>
</tr>
<tr>
<td>int</td>
<td>{-2147483648, ..., 2147483647} (32bit)</td>
<td>Integer strings that map to values within this range</td>
</tr>
<tr>
<td>double</td>
<td>IEEE double-precision 64-bit floating point numbers</td>
<td>decimal strings, exp notation numbers, special values (e.g., NaN)</td>
</tr>
<tr>
<td>float</td>
<td>single-precision 32-bit floating point numbers</td>
<td>same as double</td>
</tr>
</tbody>
</table>
Important datatypes in RDF (2)

There are also many types for dates and times:

<table>
<thead>
<tr>
<th>Name</th>
<th>Value space</th>
<th>Lexical space</th>
</tr>
</thead>
<tbody>
<tr>
<td>dateTime</td>
<td>dates with times represented by a seven-tuple consisting of year, month, day, hours, minutes, seconds, timezone offset (constrained to time-like ranges)</td>
<td>ISO-style date-time strings, e.g., 2018-10-23T11:45:30+01:00; one can write Z for offset 00:00</td>
</tr>
</tbody>
</table>

There are also partial time types, such as date, time, gYear (Gregorian year), etc.

Many further types exist: a full list can be found at https://www.w3.org/TR/2014/REC-rdf11-concepts-20140225/#section-Datatypes
**Definition 2.9:** An RDF literal is an expression of form "lexical value"^^datatype, where lexical value is a string and datatype is an IRI.

Literals are semantically interpreted to denote a value in the value space as defined by the datatype's lexical-to-value mapping. If the given string is not a valid lexical value, the literal is ill-typed.

**Note:** RDF 1.1 also allows for string literals "lexical value"; in this case XML Schema string is assumed as datatype.
Furthermore, RDF supports strings that have a specific language:

**Definition 2.10:** A language-tagged string is an expression of the form "string"@language where string is a Unicode string and language is a well-formed language tag (after BCP47). They are interpreted as pairs of strings with a (lower-cased) language tag.

The datatype of these literals is defined to be http://www.w3.org/1999/02/22-rdf-syntax-ns#langString (but this is never used in syntax).

**Example 2.11:** The strings "Pommes Frites"@de, "chips"@en-UK, and "French fries"@en-US are language-tagged.

This special case of literal is widely used in practice to encode human-readable labels.
Blank nodes

RDF also supports vertices that are not identified by a IRI, called blank nodes or bnodes.

- Intuitively, bnodes are placeholder for some specific (but unspecified) node
- Their use makes the claim: “there is something at this position”
- Similar to existentially quantified variables in logic
Blank nodes

RDF also supports vertices that are not identified by a IRI, called **blank nodes** or **bnodes**.

- Intuitively, bnodes are placeholder for some specific (but unspecified) node
- Their use makes the claim: “there is something at this position”
- Similar to existentially quantified variables in logic

**Example:** Blank nodes have historically been used for auxiliary vertices

```
https://www.dresden.de/#uri
```

```
https://example.org/coordinates
https://example.org/latitude
https://example.org/longitude
```

```
"51.049259"^^xsd:decimal
"13.73836"^^xsd:decimal
```

**Note:** Today, bnodes are largely avoided. They still occur in the RDF-encoding of the OWL Web Ontology Language, but specialised tools are used in this application anyway.
We now have defined all necessary kinds of RDF terms: IRIs, blank nodes, and literals.
We now have defined all necessary kinds of RDF terms: IRIs, blank nodes, and literals. The formal definition of RDF graph is maybe slightly different from expectations:

**Definition 2.12:** An RDF graph is a set of triples consisting of the following parts:
- a subject that is an IRI or blank node
- a predicate that is an IRI
- a object that is an IRI, blank node, or literal
RDF Graphs

We now have defined all necessary kinds of RDF terms: IRIs, blank nodes, and literals. The formal definition of RDF graph is maybe slightly different from expectations:

**Definition 2.12:** An RDF graph is a set of triples consisting of the following parts:

- a subject that is an IRI or blank node
- a predicate that is an IRI
- a object that is an IRI, blank node, or literal

**Notes:**

- This view resembles a (labelled) adjacency list encoding
- The restrictions on the use of blank nodes and literals in triples is a bit arbitrary
- RDF graphs are mostly syntactic (rather what we write than what we mean)
- In particular, literals are not interpreted when defining graphs
  - multiple ways of writing the same value lead to multiple graphs
  - ill-formed literals are allowed in graphs
Serialisations
What we outlined so far is the abstract syntax of RDF. To exchange graphs, we need concrete syntactic forms to encode RDF graphs.
What we outlined so far is the abstract syntax of RDF. To exchange graphs, we need concrete syntactic forms to encode RDF graphs.

There are numerous syntactic formats available:

- N-Triples as a simple line-based format
- Turtle adds convenient abbreviations to N-Triples
- JSON-LD for encoding RDF graphs in JSON
- RDF/XML for encoding RDF graphs in XML
- RDFa for embedding RDF graphs into HTML

Further historic/unofficial formats exist but are hardly relevant today.
N-Triples is almost the simplest format conceivable:

- Each line encodes one triple:
  - IRIs are written in pointy brackets, e.g., `<https://www.dresdenrespekt.de/>`
  - Literals are written as usual with a given type IRI, e.g., "2018-10-21"^^<http://www.w3.org/2001/XMLSchema#date> or with a language-tag, e.g., "Wir sind mehr"@de
  - Blank nodes are written as _ : stringId, where stringId is a string that identifies the blank node within the document (it has no global meaning)
  - Parts are separated by whitespace, and lines end with .

- Unicode is supported, but various escape sequences also work
- Comments are allowed after triples (nowhere else); they start with #

Full specification at https://www.w3.org/TR/n-triples/
Example

could be encoded as (line-breaks within triples for presentation only):

```xml
<https://example.org/Melitta-Bentz> <https://example.org/invention> _:1 .
_:1 <https://example.org/inventor> <https://example.org/Melitta-Bentz> .
```
N-Triples: Summary

**Advantages:**
- Very simple
- Fast and easy to parse
- Processable even with basic text-processing tools, e.g., grep

**Disadvantages:**
- Somewhat inefficient in terms of storage space
- Not particularly human-friendly (reading and writing)
The Turtle format extends N-Triples with several convenient abbreviations:

- Prefix declarations and base namespaces allow us to shorten IRIs
- If we terminate triples with ; (respectively with ,) then the next triple is assumed to start with the same subject (respectively with the same subject and predicate)
- Blank nodes can be encoded using square brackets; they might contain predicate-object pairs that refer to the blank node as subject
- More liberal support for comments (possibly on own line)
- Simpler forms for some kinds of data values

There are several other shortcuts and simplifications. Full specification at https://www.w3.org/TR/turtle/.
PREFIX and BASE by example

- BASE is used to declare a base IRI, so that we can use relative IRIs
- PREFIX is used to declare abbreviations for IRI prefixes

**Example 2.13:** We can write the previous example as follows:

```xml
BASE <https://example.org/>
PREFIX xsd: <http://www.w3.org/2001/XMLSchema#>
PREFIX rdfs: <http://www.w3.org/2000/01/rdf-schema#>

<Melitta-Bentz> rdfs:label "Melitta Bentz"@en .
<Melitta-Bentz> <birthdate> "1873-01-31"^^xsd:date .
<Melitta-Bentz> <invention> _:1 .
<https://www.dresden.de/#uri> <population> "547172"^^xsd:int .
_:1 <inventor> <Melitta-Bentz> .
```

**Note:** Relative IRIs are still written in `<` and `>` (e.g., `<birthdate>`); prefixed names are written without brackets (e.g., `rdfs:label`).
Use of semicolon by example

- If we terminate triples with ; then the next triple is assumed to start with the same subject
- If we terminate triples with , then the next triple is assumed to start with the same subject and predicate

Example 2.14: We can write the previous example as follows:

```xml
BASE <https://example.org/>
PREFIX xsd: <http://www.w3.org/2001/XMLSchema#>
PREFIX rdfs: <http://www.w3.org/2000/01/rdf-schema#>

<Melitta-Bentz> rdfs:label "Melitta Bentz"@en ;
  <birthdate> "1873-01-31"^^xsd:date ;
  <invention> _:1 ;
<https://www.dresden.de/#uri> <population> "547172"^^xsd:int .
_:1 <inventor> <Melitta-Bentz> .
```
Brackets for bnodes by example

- The expression `[]` represents a bnode (without id)
- predicate-object pairs within `[…]` are allowed to give further triples with the bnode as subject

Example 2.15: We can write the previous example as follows:

```xml
BASE <https://example.org/>
PREFIX xsd: <http://www.w3.org/2001/XMLSchema#>
PREFIX rdfs: <http://www.w3.org/2000/01/rdf-schema#>

<Melitta-Bentz> rdfs:label "Melitta Bentz"@en ;
  <birthdate>  "1873-01-31"^^xsd:date ;
  <invention> [ <inventor> <Melitta-Bentz> ] ;
<https://www.dresden.de/#uri> <population> "547172"^^xsd:int .
```
Abbreviating numbers and booleans

- Numbers can just be written without quotes and type to denote literals in default types (integer, decimal, or double)
- Booleans can also be written as true or false directly

Example 2.16: We can write the previous example as follows:

```xml
BASE <https://example.org/>
PREFIX xsd: <http://www.w3.org/2001/XMLSchema#>
PREFIX rdfs: <http://www.w3.org/2000/01/rdf-schema#>

<Melitta-Bentz> rdfs:label "Melitta Bentz"@en ;

```
Advantages:

- Still quite simple
- Not hard to parse
- Human-readable (if formatted carefully)

Disadvantages:

- Not safely processable with grep and similar tools
Other syntactic forms

There are various further syntactic forms:

- **RDF/XML**: An XML-based encoding; historically important in RDF 1.0; hard-to-parse but unable to encode all RDF graphs; not human-readable either
- **JSON-LD**: A JSON-based encoding and away of specifying how existing JSON maps to RDF; can re-use fast JSON parsers (esp. those in browsers)
- **RDFa**: An HTML embedding of RDF triples; used for HTML document annotations (e.g., with schema.org); mostly for consumption by Web crawlers
RDF Datasets

RDF 1.1 also supports datasets that consist of several graphs:

- This is useful for organising RDF data, especially within databases
- Several named graphs are identified by IRIs; there is also one default graph without any IRI
- RDF dataset = RDF data that may have more than one graph

Only some specialised syntactic forms can serialise RDF datasets with named graphs:

- N-Quads: Extension of N-Triples with optional fourth component in each line to denote graph.
- TriG: Extension of Turtle with a new feature to declare graphs (group triples of one graph in braces, with the graph IRI written before the opening brace)
- JSON-LD: Can also encode named graph

The semantics of named graphs was left open by the Working Group. Are all graphs' triples claimed, or just those in the default graph? Are the IRIs of graphs denote the resource that is the set of triples given, or something else? {currently application-dependent}

\(\rightarrow\) currently application-dependent
Summary

RDF is a W3C standard for describing directed, edge-labelled graphs in an interoperable way.

It identifies vertices and edge-types using IRIs, and it can use many datatypes.

Several syntactic formats exist for exchanging RDF data.

What’s next?

- How can we encode data in RDF?
- Where can we get RDF data? Application examples?
- How can we query and analyse such graphs?
