### **Description Logics - Reasoning with Data**

Lecture 6, 3rd Nov 2025 // Foundations of Knowledge Representation, WS 2025/26

### Recap

- For description logic knowledge bases, there are various relevant reasoning problems.
- All can be reduced to knowledge base (in)consistency.
- The basic description logic  $\mathcal{ALC}$  can be extended in various ways:

	0	- <b>J</b> - ·
_	Inverse Roles	J
_	(Qualified) Number Restrictions	(Q) N
-	Nominals	O
-	Role Hierarchies	${\mathcal H}$
-	Transitive Roles	$\mathcal{ALC} \leadsto \mathbb{S}$ , $\cdot_{R^+}$

- Description Logics have close connections with propositional modal logic ...
- ...and with the two-variable fragments of first-order logic (with counting quantifiers)

## **Reasoning with Data**

So far we have focused on terminological reasoning

- TBoxes represent general, conceptual domain knowledge
- Terminological reasoning is key to design error-free TBoxes

New Scenario: Ontology-based data access (OBDA)

- We have built an (error-free) TBox for our domain
- We want to populate ontology with data (add an ABox)
   ABox & TBox should be compatible (no inconsistencies)
- · Then, we can query the data
  - TBox provides vocabulary for queries
  - Answers reflect both TBox knowledge and ABox data

# **Compatibility of Data and Knowledge**

The ABox data should be compatible with the TBox knowledge

```
\mathfrak{T} = \{ \mathsf{GradSt} \sqcap \mathsf{UnderGradSt} \sqsubseteq \bot \}
\mathcal{A} = \{ \mathsf{John} : \mathsf{GradSt}, \mathsf{John} : \mathsf{UnderGradSt} \}
```

Nothing wrong with the TBox

Nothing wrong with the ABox

There is an obvious error when putting them together

To detect these situations we use the following problem:

#### **Knowledge Base consistency:**

```
Input: knowledge base \mathcal{K} = (\mathcal{T}, \mathcal{A}).
Answer: true iff a model \mathcal{T} \models \mathcal{K} exists.
```

In a FOL setting,  $\mathcal K$  is consistent if and only if  $\pi(\mathcal K)$  is satisfiable.

## **Tableau Algorithm for KB Consistency**

Tableau-based knowledge base consistency algorithm:

- Input: Knowledge Base  $\mathfrak{K} = (\mathfrak{T}, \mathcal{A})$
- Output: true iff  $\mathcal{K} = (\mathcal{T}, \mathcal{A})$  is consistent
- 1. Start with input ABox A
- 2. Apply expansion rules until completion or clash
- 3. Blocking only involves individuals not occurring in  ${\mathcal A}$

Exploit forest-model property: construct forest-shaped extended ABox root (original ABox) individuals can be arbitrarily connected new individuals (introduced by  $\exists$ -rule) form trees

## **Querying the Data**

It does not make sense to query an inconsistent  $\mathcal{K}$  (previous example)

- An inconsistent  $\mathfrak X$  entails all formulas.
- We (typically) fix inconsistencies before we start asking queries.

Once we have determined that  $\mathcal{K}$  is consistent, we want to query the data:

- Which children are affected by a juvenile arthritis?
- Which drugs are used to treat JRA?
- Who is affected by an arthritis and is allergic to steroids?

Similar to the types of queries one would pose to a database.

```
SELECT Child.cname
FROM Child, Affects, JuvArth
WHERE Child.cname = Affects.cname AND
Affects.dname = JuvArth.dname
```

## **Querying the Data: Simple Queries (1)**

The basic data queries ask for all the instances of a concept:

$$q_1(x) = \text{Child}(x)$$
 Set of children?

$$q_2(x) = (\text{Dis} \sqcap \exists Damages.Joint)(x)$$
 Set of diseases affecting a joint?

How to (naively) answer these queries? Try each individual name!

ABox 
$$A$$
 TBox  $T$  ( $X = (T, A)$ )

(JRA, John): Affects JuvDis 
$$\sqsubseteq \exists Affects$$
. Child  $\sqcap \forall Affects$ . Child

(JRA, Mary): 
$$Affects$$
 Arth  $\sqsubseteq \exists Damages$ . Joint

$$JuvArth \sqsubseteq Arth \sqcap JuvDis$$

$$\mathcal{K} \models \mathsf{JRA} : \mathsf{Child}?$$
 No. JRA is not an answer to  $q_1$ 

$$\mathfrak{K} \models John: Child?$$
 Yes! John is an answer to  $q_1$ 

$$\mathfrak{K} \models \mathsf{Mary} : \mathsf{Child}? \ \mathit{Yes}! \ \mathsf{Mary} \ \mathsf{is} \ \mathsf{an} \ \mathsf{answer} \ \mathsf{to} \ q_1$$

## Querying the Data: Simple Queries (2)

So, we are interested in the following decision problem:

#### **Concept Instance Checking:**

Input: triple  $\langle a, C, \mathcal{K} \rangle$ ,

with individual name a, concept C and KB  $\mathfrak{K}$ .

Answer: true iff  $\mathfrak{K} \models a : C$ 

In ALC (and extensions) this problem is reducible to KB consistency:

$$(\mathfrak{T}, \mathcal{A}) \models \mathsf{a} : \mathsf{C}$$
 iff  $(\mathfrak{T}, \mathcal{A} \cup$ 

ff 
$$(\mathfrak{T}, \mathcal{A})$$

## **Querying the Data: Simple Queries (2)**

So, we are interested in the following decision problem:

#### **Concept Instance Checking:**

Input: triple  $\langle a, C, \mathcal{K} \rangle$ ,

with individual name a, concept C and KB  $\mathfrak{K}$ .

Answer: true iff  $\mathfrak{K} \models a : C$ 

In ALC (and extensions) this problem is reducible to KB consistency:

$$(\mathfrak{T},\mathcal{A})\models a:C$$
 iff  $(\mathfrak{T},\mathcal{A}\cup\{a:\neg\mathsf{C}\})$  inconsistent

Note that we can assume, w.l.o.g., that *C* is a concept name:

$$(\mathfrak{I}, \mathcal{A}) \models a: C$$
 iff  $(\mathfrak{I} \cup \{X \equiv C\}, \mathcal{A}) \models a: X$ 

where X is a concept name that does not occur in  $\mathcal{T}$  or  $\mathcal{A}$ .

## **Querying the Data: Simple Queries (3)**

What about instances of a role:

$$q_2(x,y) = hasChild(x,y)$$
 Set of parent-child tuples?

How to (naively) answer these queries? Try each pair of individuals!

ABox  $\mathcal{A}$  TBox  $\mathcal{T}$  ( $\mathcal{K} = (\mathcal{T}, \mathcal{A})$ )

JRA: JuvArth JuvDis  $\sqsubseteq \exists Affects$ . Child  $\sqcap \forall Affects$ . Child

(JRA, Mary): Affects Adult  $\sqsubseteq \neg$ Child

(John, Mary): hasChild Arth  $\sqsubseteq \exists Damages$ . Joint

 $JuvArth \sqsubseteq Arth \sqcap JuvDis$ 

 $\mathcal{K} \models (John, John): hasChild?$  No. (John, John) is not an answer to  $q_2$ 

 $\mathcal{K} \models (John, Mary): hasChild? Yes! (John, Mary) is an answer to <math>q_2$ 

 $\mathcal{K} \models (John, JRA): hasChild?$  No. (John, John) is not an answer to  $q_2$ 

# **Querying the Data: Simple Queries (4)**

So, we are interested in the following decision problem:

#### **Role Instance Checking:**

Input: triple  $\langle (a, b), R, \mathcal{K} \rangle$ ,

with a pair of individual names (a, b), role  $\it R$  and KB  $\it X$ .

Answer: true iff  $\mathcal{K} \models (a, b): R$ 

Can this problem be reduced to knowledge base consistency?

$$(\Upsilon, A) \models (a, b) : R \text{ iff } (\Upsilon, A \cup$$

) is inconsistent

## **Querying the Data: Simple Queries (4)**

So, we are interested in the following decision problem:

#### **Role Instance Checking:**

Input: triple  $\langle (a, b), R, \mathcal{K} \rangle$ ,

with a pair of individual names (a, b), role  $\it R$  and KB  $\it X$ .

Answer: true iff  $\mathcal{K} \models (a, b): R$ 

Can this problem be reduced to knowledge base consistency?

 $(\mathfrak{T}, \mathcal{A}) \models (\mathsf{a}, \mathsf{b}) : R \quad \text{iff} \quad (\mathfrak{T}, \mathcal{A} \cup \{\mathsf{a} : \forall R.\mathsf{X}, \mathsf{b} : \neg \mathsf{X}\}) \text{ is inconsistent}$ 

where X is a concept name that does not occur in  $\mathfrak{T}$  or  $\mathcal{A}$ .

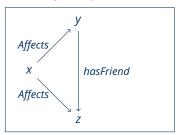

## **Limitations of Concept-based Queries**

Some natural queries cannot be expressed using a concept:

$$q(y) = \exists x \exists z (Affects(x, y) \land Affects(x, z) \land hasFriend(y, z))$$

Set of people (*y*) affected by the same disease as a friend?

#### Query Graph:

We can only represent tree-like queries as concepts

Related to the tree model property of DLs

We need a more expressive query language ...

## **Conjunctive Queries**

The language of conjunctive queries

- Generalises concept-based queries in a natural way arbitrarily-shaped queries vs. tree-like queries
- Widely used as a query language in databases
   Corresponds to Select-Project-Join fragment of relational algebra
   Fragment of relational calculus using only ∃ and ∧
- Implemented in most DBMS

We next study the problem of CQ answering over DL knowledge bases

We will not study the problem of answering FOL queries over DL KBs

- → Corresponds to general relational calculus queries.
- → Leads to an undecidable decision problem.

## **Conjunctive Queries - Definition**

#### Conjunctive query

Let **V** be a set of variables. A term *t* is a variable from **V** or an individual name from **I**.

A conjunctive query (CQ) q has the form  $\exists x_1 \cdots \exists x_k (\alpha_1 \land \cdots \land \alpha_n)$  where

- $k \ge 0, n \ge 1, x_1, \dots, x_k \in \mathbf{V}$
- each  $\alpha_i$  is a concept atom A(t) or a role atom r(t, t') with  $A \in \mathbb{C}$ ,  $r \in \mathbb{R}$ , and t, t' terms
- x<sub>1</sub>,...,x<sub>k</sub> are called quantified variables;
   all other variables in q are called answer variables
- the arity of q is the number of answer variables
- q is called Boolean if it has arity zero

To indicate that the answer variables in a CQ q are  $\vec{x}$ , we often write  $q(\vec{x})$  instead of just q.

## **Example Conjunctive Queries**

1. Return all pairs of individual names (a, b) such that a is a professor who supervises student b:

$$q_1(x_1, x_2) = \text{Professor}(x_1) \land \text{supervises}(x_1, x_2) \land \text{Student}(x_2).$$

2. Return all individual names a such that a is a student supervised by some professor:

$$q_2(x) = \exists y \; (Professor(y) \land supervises(y, \underline{x}) \land Student(\underline{x})).$$

3. Return all pairs of students supervised by the same professor:

$$q_3(x_1, x_2) = \exists y \, (\text{Professor}(y) \land \text{supervises}(y, \underline{x_1}) \land \text{supervises}(y, \underline{x_2}) \land \text{Student}(x_1) \land \text{Student}(x_2)).$$

4. Return all students supervised by professor smith (an individual name):

$$q_4(x) = \text{supervises(smith}, x) \land \text{Student}(x).$$

### **Answers on an Interpretation**

We first define query answers on a given interpretation  $\mathfrak{I}$ .

#### Definition

Let q be a conjunctive query and  $\mathfrak I$  an interpretation. We use term(q) to denote the terms in q.

A match of q in  $\mathcal{I}$  is a mapping  $\pi$ : term $(q) \rightarrow \Delta^{\mathcal{I}}$  such that

- $\pi(a) = a^{\mathfrak{I}}$  for all  $a \in \text{term}(q) \cap \mathbf{I}$ ,
- $\pi(t) \in A^{\mathfrak{I}}$  for all concept atoms A(t) in q, and
- $(\pi(t_1), \pi(t_2)) \in r^{\Im}$  for all role atoms  $r(t_1, t_2)$  in q.

Let  $\vec{x} = x_1, \dots, x_k$  be the answer variables in q and  $\vec{a} = a_1, \dots, a_k$  be individual names from **I**. We call the match  $\pi$  of q in  $\mathfrak{I}$  an  $\vec{a}$ -match if  $\pi(x_i) = a_i^{\mathfrak{I}}$  for 1 < i < k.

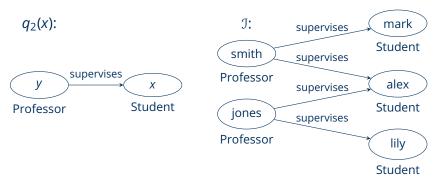

We say that  $\vec{a}$  is an answer to q on  $\mathfrak{I}$  if there is an  $\vec{a}$ -match  $\pi$  of q in  $\mathfrak{I}$ .

We use ans(q,  $\Im$ ) to denote the set of all answers to q on  $\Im$ .

### Answers on Interpretation $\mathfrak I$

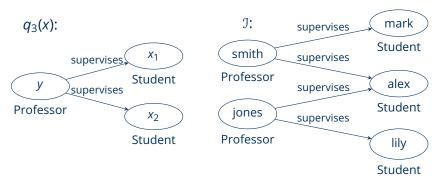

$$q_2(x) = \exists y (\mathsf{Professor}(y) \land \mathsf{supervises}(y, \underline{x}) \land \mathsf{Student}(\underline{x}))$$

There are 3 answers to  $q_2(x)$  on  $\mathfrak{I}$ : mark, alex, and lily. Note that a match is a homomorphism from the query to the interpretation (both viewed as a graphs).

### Answers on Interpretation $\mathfrak I$

$$q_3(x_1, x_2) = \exists y \, (\text{Professor}(y) \land \text{supervises}(y, \underline{x_1}) \land \text{supervises}(y, \underline{x_2}) \land \text{Student}(x_1) \land \text{Student}(x_2)).$$

There are 7 answers to  $q_3(x_1, x_2)$  on  $\mathfrak{I}$ , including (mark, alex), (alex, lily), (lily, alex) and (mark, mark). Note that a match need not be injective.

### **Certain Answers**

Usually we are interested in answers on a KB, which may have many models. In this case, so-called certain answers provide a natural semantics.

#### Definition

Let q be a CQ and  $\mathcal{K} = (\mathcal{T}, \mathcal{A})$  be a KB.

We say that  $\vec{a}$  is a certain answer to q on  $\mathfrak{K}$  if

- all individual names from  $\vec{a}$  occur in A
- $\vec{a} \in ans(q, I)$  for every model I of K

We use  $cert(q, \mathcal{K})$  to denote the set of all certain answers to q on  $\mathcal{K}$ :

$$\operatorname{cert}(q,\mathfrak{K}) = \bigcap_{\mathfrak{I} \models \mathfrak{K}} \operatorname{ans}(q,\mathfrak{I})$$

Consider the  $\mathcal{ALCI}$  KB  $\mathcal{K} = (\mathcal{T}, \mathcal{A})$ :  $\mathcal{T} = \{ \text{Student} \sqsubseteq \exists \text{supervises}^-. \text{Professor} \},$   $\mathcal{A} = \{ \text{smith} : \text{Professor}, \text{mark} : \text{Student}, \text{alex} : \text{Student}, \text{lily} : \text{Student},$   $(\text{smith}, \text{mark}) : \text{supervises}, (\text{smith}, \text{alex}) : \text{supervises} \}.$ 

•  $q_4(x) = \text{supervises}(\text{smith}, \underline{x}) \land \text{Student}(\underline{x});$ 

•  $q_2(x) = \exists y (Professor(y) \land supervises(y, \underline{x}) \land Student(\underline{x}));$ 

•  $q_1(x_1, x_2) = \text{Professor}(x_1) \land \text{supervises}(x_1, x_2) \land \text{Student}(x_2);$ 

Consider the  $\mathcal{ALCI}$  KB  $\mathcal{K} = (\mathcal{T}, \mathcal{A})$ :  $\mathcal{T} = \{ \text{Student} \sqsubseteq \exists supervises^-. \text{Professor} \},$   $\mathcal{A} = \{ \text{smith} : \text{Professor}, \text{mark} : \text{Student}, \text{alex} : \text{Student}, \text{lily} : \text{Student},$   $(\text{smith}, \text{mark}) : supervises, (\text{smith}, \text{alex}) : supervises \}.$ 

- $q_4(x) = \text{supervises}(\text{smith}, \underline{x}) \land \text{Student}(\underline{x}); \text{ cert}(q_4, \mathcal{K}) = \{\text{mark}, \text{alex}\}: \text{ there are models of } \mathcal{K} \text{ in which smith supervises other students, but only mark and alex are supervised by smith in } all \text{ models.}$
- $q_2(x) = \exists y (Professor(y) \land supervises(y, \underline{x}) \land Student(\underline{x}));$

•  $q_1(x_1, x_2) = \text{Professor}(\underline{x_1}) \land \text{supervises}(\underline{x_1}, \underline{x_2}) \land \text{Student}(\underline{x_2});$ 

```
Consider the \mathcal{ALCI} KB \mathcal{K} = (\mathcal{T}, \mathcal{A}):
\mathcal{T} = \{ \text{Student} \sqsubseteq \exists \text{supervises}^-. \text{Professor} \},
\mathcal{A} = \{ \text{smith} : \text{Professor}, \text{mark} : \text{Student}, \text{alex} : \text{Student}, \text{lily} : \text{Student},
(\text{smith}, \text{mark}) : \text{supervises}, (\text{smith}, \text{alex}) : \text{supervises} \}.
```

- $q_4(x) = \text{supervises}(\text{smith}, \underline{x}) \land \text{Student}(\underline{x}); \text{ cert}(q_4, \mathcal{K}) = \{\text{mark}, \text{alex}\}: \text{ there are models of } \mathcal{K} \text{ in which smith supervises other students, but only mark and alex are supervised by smith in$ *all*models.
- q<sub>2</sub>(x) = ∃y(Professor(y) ∧ supervises(y, x) ∧ Student(x));
   cert(q<sub>2</sub>, X) = {mark, alex, lily}: note that lily is included because she is a student and thus the TBox enforces that in every model of X she has a supervisor who is a professor.
- $q_1(x_1, x_2) = \text{Professor}(x_1) \land \text{supervises}(x_1, x_2) \land \text{Student}(x_2);$

```
Consider the \mathcal{ALCI} KB \mathcal{K} = (\mathcal{T}, \mathcal{A}):
\mathcal{T} = \{ \text{Student} \sqsubseteq \exists supervises^-. \text{Professor} \},
\mathcal{A} = \{ \text{smith} : \text{Professor}, \text{mark} : \text{Student}, \text{alex} : \text{Student}, \text{lily} : \text{Student},
(\text{smith}, \text{mark}) : supervises, (\text{smith}, \text{alex}) : supervises \}.
```

- $q_4(x) = \text{supervises}(\text{smith}, \underline{x}) \land \text{Student}(\underline{x}); \text{ cert}(q_4, \mathcal{K}) = \{\text{mark}, \text{alex}\}: \text{ there are models of } \mathcal{K} \text{ in which smith supervises other students, but only mark and alex are supervised by smith in$ *all*models.
- q<sub>2</sub>(x) = ∃y(Professor(y) ∧ supervises(y, x) ∧ Student(x));
   cert(q<sub>2</sub>, X) = {mark, alex, lily}: note that lily is included because she is a student and thus the TBox enforces that in every model of X she has a supervisor who is a professor.
- $q_1(x_1, x_2) = \text{Professor}(\underline{x_1}) \land \text{supervises}(\underline{x_1}, \underline{x_2}) \land \text{Student}(\underline{x_2});$   $\text{cert}(q_1, \mathcal{K}) = \{(\text{smith, mark}), (\text{smith, alex})\}: \text{lily always has a supervisor,}$  but there is no supervisor (known by name) on which all models agree.

## **Boolean Conjunctive Query Answering**

(Arbitrary) CQ answering reduces to Boolean CQ answering:

Given query q of arity n and  $\mathcal{K} = (\mathfrak{I}, \mathcal{A})$  in which m individual names occur.

- Iterate through m<sup>n</sup> tuples of arity n
- For each tuple  $\vec{a} = (a_1, \dots, a_n)$  create a Boolean query  $q_{\vec{a}}$  by replacing the *i*th answer variable with  $a_i$
- $\vec{a} \in \text{cert}(q, \mathcal{K}) \text{ iff } \mathcal{K} \models q_{\vec{a}}$

### **Boolean Conjunctive Query Entailment:**

Input: a pair  $\langle \mathfrak{K}, q \rangle$ 

with  $\mathfrak{K}$  a KB and q a Boolean CQ.

Answer: true iff  $\mathfrak{I} \models q$  for each  $\mathfrak{I} \models \mathfrak{K}$ .

This problem is not trivially reducible to knowledge base consistency.

It is ExpTime-complete for  $\mathcal{ALC}$ , the same as consistency. (proof beyond this course)

## **Boolean Conjunctive Query Answering**

Many types of query can be reduced to KB consistency:

- Concept and role instance queries, e.g., q() = C(a) and q() = r(a,b)
- Fully ground queries, e.g.,  $q() = C(a) \land D(b) \land r(a,b)$  check each atom independently
- Forest shaped queries, e.g.,  $q() = \exists x (C(a) \land D(x) \land r(a,x))$  roll up tree parts of query

Reduction may or may not be possible in general (possible for SHIQ; open problem for SHOIQ).

# **Conjunctive Query Answering (1)**

How to interpret the answer to a Boolean Query?

 $(\mathcal{K} = (\mathcal{T}, \mathcal{A}))$

```

#### **Ontologies vs. Database Systems**

#### **Conceptual DB-Schema:**

- Typically formulated as an ER or UML diagram (used in DB design)
- Schema leads to a set of FOL-based constraints.
- Constraints are used to check conformance of the data
- Constraints are disregarded for query answering
  - → In databases, query answering is a FOL *model checking* problem.

#### **Description Logic TBoxes:**

- Formulated in a Description Logic (fragment of FOL)
- TBox axioms are used to check conformance of the data
   The way this is done differs from DBs
- TBox axioms participate in query answering
  - → In description logics, query answering is a FOL *entailment* problem.

# **KB Consistency: Practicality Issues**

- Addition of ABox may greatly exacerbate practicality problems
  - No obvious limit to size of data could be millions or even billions of individuals
  - Tableau algorithm applied to whole ABox
- Optimisations can ameliorate but not eliminate problem
- Can exploit decomposition of an ABox:
  - A can be decomposed into a set of disjoint connected components  $\{A_1, \ldots, A_n\}$  such that:

$$\mathcal{A} = \mathcal{A}_1 \cup \ldots \cup \mathcal{A}_n$$
  
 
$$\forall_{1 \leq i \leq j \leq n} \operatorname{ind}(\mathcal{A}_i) \cap \operatorname{ind}(\mathcal{A}_j) = \emptyset$$

where ind( $A_i$ ) is the set of individuals (constants) occurring in  $A_i$ 

• An  $\mathcal{ALC}$  KB  $(\mathcal{T}, \mathcal{A})$  is consistent iff  $(\mathcal{T}, \mathcal{A}_i)$  is consistent for each  $\mathcal{A}_i$  in a decomposition  $\{\mathcal{A}_1, \dots, \mathcal{A}_n\}$  of  $\mathcal{A}$ 

#### **ABox Decomposition: Example**

JRA: JuvArth

(JRA, Mary): Affects

(John, Mary): hasChild

(Paul, Miranda): hasChild

Paul: Adult

JuvDis  $\sqsubseteq \exists Affects.Child \sqcap \forall Affects.Child$ 

 $\exists hasChild. \top \sqsubseteq Adult$ 

Adult 

¬Child

Arth  $\sqsubseteq \exists Damages.$ Joint

JuvArth

JuvDis

#### **ABox Decomposition: Example**

JRA:JuvArth

(JRA, Mary): Affects

(John, Mary): hasChild

(Paul, Miranda): hasChild

Paul: Adult

JuvDis  $\sqsubseteq \exists Affects$ .Child  $\sqcap \forall Affects$ .Child

 $\exists hasChild. \top \sqsubseteq Adult$ 

Adult ⊑ ¬Child

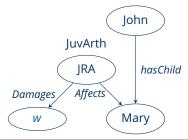

Arth  $\sqsubseteq \exists Damages.$ Joint

JuvArth 

Arth 

JuvDis

Perform separate consistency tests on the disjoint connected components:

#### **Query Answering: Practicality Issues**

Recall our example query

$$q(y) = \exists x \exists z (Affects(x, y) \land Affects(x, z) \land hasFriend(y, z))$$

- To answer this query we have to:
  - check for each individual a occurring in  $\mathcal{A}$  if  $(\mathfrak{T},\mathcal{A})\models q_{[y/a]}$ , where  $q_{[y/a]}$  is the Boolean CQ

$$q() = \exists x \exists z (Affects(x, a) \land Affects(x, z) \land hasFriend(a, z))$$

- checking  $(\mathfrak{I}, \mathcal{A}) \models q_{[y/a]}$  involves performing (possibly many) consistency tests
- each test could be very costly
- And what if we change the query to

$$q(x, y, z) = Affects(x, y) \land Affects(x, z) \land hasFriend(y, z)$$
?

• In general, there are  $n^m$  "candidate" answer tuples, where n is the number of individuals occurring in A and m the arity of the query

#### **Optimised Query Answering**

Many optimisations are possible, for example:

• Exploit the fact that we can't entail ABox roles in  $\mathcal{ALC}$ , that is:

$$(\mathfrak{T},\mathcal{A})\models R(a,b) \text{ iff } R(a,b)\in\mathcal{A}$$

- Only check candidate tuples with relevant relational structure
- So for

$$q(y,z) = \exists x (JuvArth(x) \land Affects(x,y) \land hasFriend(y,z))$$

only check tuples (a, b) such that

$$hasFriend(a,b) \in A$$

and for these only need to check Boolean CQ:

$$\exists x \ ( JuvArth(x) \land Affects(x, a) \land Affects(x, b) )$$

#### **Conflicting Requirements**

Ontology-based data access applications require:

- Very expressive ontology languages
   As large fragment of FOL as possible
- Powerful query languagesAs large fragment of SQL as possible
- 3. Efficient query answering algorithms

  Low complexity, easy to optimise

#### The requirements are in conflict!

→ We need to make compromises.

#### **Conclusion**

- DL KB consistency can be decided using tableau algorithms
   Idea: Make implicit inconsistencies explicit/construct model
- Query answering for DL KBs is understood as FOL entailment
- Conjunctive Queries constitute natural query language
- CQs induce answers on a single interpretation, and certain answers on a KB
- Boolean CQ Entailment is not trivially reducible to KB consistency
- In contrast, CQ Entailment in databases is understood as FOL model checking
